

The FreeM Manual

THE OFFICIAL MANUAL OF FREEM
Version 0.3.4

John P. Willis

This manual is for FreeM, (version 0.3.4), which is a free and open-source implementation of the M programming language and database system.

Introduction

FreeM started its life as *FreeMUMPS*, written for MS-DOS and ported to Linux and SCO UNIX by a mysterious individual going by the name of "Shalom ha-Ashkenaz". It was released to MUG Deutschland in 1998, and maintenance was taken over by the Generic Universal M Project thereafter, which changed its name first to Public Standard MUMPS and then by popular request to FreeM.

When GT.M was open-sourced in late 1999, FreeM and GUMP were essentially abandoned. L.D. Landis, the owner of the original GUMP SourceForge project, and one of FreeM's significant contributors, passed maintenance of FreeM and ownership of its SourceForge project to John Willis in 2014. At this point, FreeM would not compile or run on modern Linux systems, so steps were taken to remedy the most pressing issues in the codebase. Limitations on the terminal size (previously hard-coded to 80x25) were lifted, and new `$VIEW` functions were added to retrieve the terminal size information. `$X` and `$Y` intrinsic special variables were updated to support arbitrary terminal sizes, and FreeM was once again able to build and run.

In February of 2020, work began in earnest to build a development and support infrastructure for FreeM and begin the careful process of refining it into a more stable and robust product.

Production Readiness

FreeM is not yet production-ready. There are several show-stopping bugs that preclude a general release for public use:

- SSVs, aside from `^$JOB`, are not implemented.
- `VIEW` commands and `$VIEW` functions are used extensively to configure and inspect the run-time behavior of FreeM, rather than the "canonical" SSV-based approach.

Contributors

Current contributors denoted with a + following their name and role.

- Shalom ha-Ashkenaz (Original Implementer)
- John Best (IBM i and OS/400)
- Jon Diamond (Library, Utilities, Conformance)
- Winfried Gerum (Code, Advice, MTA coordination)
- Greg Kreis (Hardhats coordination, Dependencies)
- Larry Landis (Coordination, Code, Documentation)
- Frederick D.S. Marshall (MDC Standards Conformance) +
- Lloyd Milligan (Code, Testing, Documentation)
- Steve Morris (Code, Microsoft)
- John Murray (Code, Conformance)
- Wilhelm Pastoors (Testing, Documentation)
- Kate Schell (Coordination, Conformance, MTA, MDC, Advice)
- Lyle Schofield (Advice, Prioritization, Tracking, Project Management)

- Jim Stefanik (Linux on s390x, IBM AIX, IBM z/OS)
- Axel Trocha (Code, Utilities)
- Dick Walters (Project Lead, Chief Coordinator, MTA)
- David Whitten (QA Test Suite, MDC, Advice) +
- David Wicksell (Debugging, Code, Testing) +
- John Willis (Current Maintainer and Project Lead) +
- Steve Zeck (Code)

1 FreeM Invocation

1.1 Synopsis

```
$ ./freem [OPTIONS...] [[-r <entryref>] | [--routine=<entryref>]]
```

When FreeM loads, it searches the `SYSTEM` namespace for the `^%ZFREEEM` routine, and begins executing it.

When `-r` or `--routine` are passed on the command line, FreeM will load and run the specified routine instead of `^%ZFREEEM`. Beginning with FreeM 0.1.7, routines invoked in this manner are no longer required to perform their own namespace setup with `VIEW` commands.

1.2 Command-Line Options

`-h`, `--hardcopy`

Enables hardcopy mode, echoing all output to a disk file. By default, this disk file is `\$freem_base/<namespace-name>/freem.hardcopy`, but can be changed with the following command:

```
USER> VIEW 13:"</path/to/hardcopy/file>"
```

The file used for hardcopy mode may also be specified in `/etc/freem.conf` or `~/freemrc`.

`-f`, `--filter`

Allows your M routines to be used as UNIX filters.

`-n`, `--noclear`

Disables automatic screen clearing when FreeM loads.

`-s`, `--standard`

Restricts the use of non-standard language features, including `$Z...` intrinsic special variables, `$Z...` intrinsic functions, `Z...` commands, as well as `VIEW` and `$VIEW`.

`-i`, `--import`

Causes your UNIX environment variables to be imported into FreeM's local symbol table.

`-r <entryref>`, `--routine=<entryref>`

Causes `<entryref>` to be executed at load, instead of `^%ZFREEEM`.

`-n <namespace-name>`, `--namespace=<namespace-name>`

Selects the FreeM namespace to be entered on startup. Must be defined in `/etc/freem.conf`.

1.3 Using FreeM for Shell Scripting

FreeM M routines can be used as shell scripts by providing a *shebang* line beginning with `#!/path/to/freem` as the first line of the routine. The following example presumes that FreeM is installed at `/usr/local/bin/freem` and uses the `USER` namespace:

```
#!/usr/local/bin/freem
MYSCRIPT ;
  SET ^$JOB($JOB,"NAMESPACE")="USER"
  WRITE "This is output from an M routine used as a shell script.",!
Q
```

Currently, the script needs to have a `.m` file extension. You will also need to select an appropriate namespace in your script using the `SET ^$JOB($JOB,"NAMESPACE")=<namespace>` command before attempting to call other routines or access globals.

You will also need to set the script's permissions to *executable* in order for this to work:

```
$ chmod +x myscript.m
```

2 The FreeM Direct-Mode Environment

The FreeM direct-mode environment is the mode entered when FreeM is loaded without the use of ‘-r <entryref>’ or ‘--routine=<entryref>’:

```
FreeM 0.3.4    Copyright (C) 2020 Coherent Logic Development LLC    Namespace: SYST
PID:          24420
Principal I/O: 0: "/dev/pts/19"
```

```
SYSTEM>
```

The prompt (SYSTEM>) indicates the currently-active namespace. If any uncommitted direct-mode transactions have been started, the prompt will change to reflect the current value of \$TLEVEL:

```
TL1:SYSTEM>
```

In the above example, TL1 indicates that \$TLEVEL is currently 1.

2.1 Direct-Mode Commands

When you are in direct mode, in addition to M commands, a number of internal commands are available to help developers be more productive:

? Accesses FreeM online help. Requires GNU `info(1)` to be installed on your local system.

history Prints a list of all the direct-mode commands you have entered across all sessions.

rcl <history-index>
 Allows you to recall command number <history-index> and run it again. Obtain the value for <history-index> from the output of the `history` command.

!<external-command>
 Invokes a shell to run <external-command> from within FreeM. This temporarily disables SIGALRM handling in FreeM, which may interrupt the use of event-driven M programming commands including `ESTART` and `ESTOP`.

If the < character is supplied immediately preceding <external-command>, FreeM will append the contents of M local variable % to <external-command> as standard input.

If the > character is supplied immediately preceding <external-command>, FreeM will take the standard output stream of <external-command> and store it in M local variable %.

% contains the number of lines in the input or output. %(1) .. %(n) contains the data for lines 1-n.

tdump Writes detailed information about the status of any pending transactions to \$PRINCIPAL.

If you issue a `HALT` command at the direct-mode prompt, you will exit out of FreeM. However, if you issue a `HALT` command when `$TLEVEL` is greater than zero, you will be given the opportunity to commit or rollback any pending transactions:

```
USER> TSTART
```

```
TL1:USER> SET ^MYGLOBAL=1
```

```
TL1:USER> HALT
```

```
UNCOMMITTED TRANSACTIONS EXIST:
```

```
$TLEVEL 1*
```

```
Operations for Transaction ID: k8xj1de
```

```
1: action = 0 key = ^MYGLOBAL data = 1
```

```
Would you like to c)ommit or r)ollback the above transactions and their operations? ($
```

```
Transactions have been rolled back.
```

In the above example, the user selected `r` to rollback the single pending transaction.

2.2 REPL Functionality

FreeM direct mode allows you to enter M expressions directly from the direct-mode prompt, as long as they begin with a number:

```
USER> S DENOM=10
```

```
USER> 100/DENOM
```

```
10
```

```
USER>
```

Such expressions will be immediately evaluated, and the result printed on `$PRINCIPAL`.

3 Intrinsic Special Variables

3.1 \$DEVICE

Returns the status of the device currently in use, and is writable.

If \$DEVICE returns *1*, an error condition exists on the current device.

3.2 \$ECODE

Returns a comma-delimited list of error conditions currently present, and is writable. An empty \$ECODE indicates no errors.

FreeM currently sets \$ECODE only for errors established by the M Development Committee.

Setting \$ECODE has no effect, as FreeM does not currently implement standard error-handling with \$ETRAP.

3.3 \$ESTACK

Returns an empty string, as FreeM does not currently implement standard error-handling with \$ETRAP.

3.4 \$ETRAP

Returns an empty string and is writable, but unused as FreeM does not currently implement standard error-handling with \$ETRAP.

3.5 \$HOROLOG

Returns a string containing the current date and time as `<days>`, `<seconds>`, where `<days>` represents the number of days since the M epoch (midnight on 31 December 1840), and `<seconds>` represents the number of seconds since the most recent midnight.

3.6 \$IO

Represents the current input/output device. Read-only.

3.7 \$JOB

Represents the process ID of the FreeM instance currently in use.

3.8 \$KEY

Represents the sequence of control characters that terminated the last READ command on \$IO.

3.9 \$PRINCIPAL

Represents the primary input/output device. Usually a terminal or virtual terminal.

3.10 \$QUIT

If the current execution context was invoked as an extrinsic function, `$QUIT` returns `1`. Otherwise, returns `0`.

When `$QUIT` returns `1`, a subsequent `QUIT` command must have an argument.

3.11 \$STACK

Represents the current stack level.

3.12 \$STORAGE

Represents the number of bytes of free space available in FreeM's heap.

3.13 \$SYSTEM

Returns the MDC system ID of FreeM.

3.14 \$TEST

`$TEST` is a writable, `NEW`-able ISV that is `1` if the most recently evaluated expression was *true*. Otherwise, returns `0`.

`$TEST` is implicitly `NEW`ed when entering a new stack frame for extrinsic functions and argumentless `DO`. `$TEST` is *not* implicitly `NEW`ed when a new stack frame is entered with an argumented `DO`.

3.15 \$TLEVEL

Returns a numeric value indicating the current level of transaction nesting in the process. When `$TLEVEL` is greater than `0`, uncommitted transactions exist.

3.16 \$TRESTART

Returns an empty string, as FreeM transaction processing does not yet support restartable transactions.

3.17 \$X

Represents the current column position of the FreeM cursor.

Non-Standard Behavior

In FreeM, setting `$X` will move the FreeM cursor.

3.18 \$Y

Represents the current row position of the FreeM cursor.

Non-Standard Behavior

In FreeM, setting `$Y` will move the FreeM cursor.

3.19 \$ZA

On the HOME device, always 0. On other devices, represents the byte offset to the beginning of the file.

3.20 \$ZB

Represents the last keystroke.

3.21 \$ZCONTROLC

3.22 \$ZDATE

Returns the current date, in YYYY/MM/DD format.

3.23 \$ZERROR

Returns the last error message.

3.24 \$ZF

3.25 \$ZHOROLOG

Output \$HOROLOG-style time, with the addition of milliseconds.

3.26 \$ZINRPT

Gets or sets the interrupt enable/disable flag.

3.27 \$ZJOB

Returns the \$JOB value of the parent process (used in subroutines started with the JOB command).

3.28 \$ZLOCAL

Returns the last local variable referenced.

3.29 \$ZMATCHCONTROL

Returns control characters.

3.30 \$ZMATCHNUMERIC

Returns all numbers 0-9.

3.31 \$ZMATCHPUNCTUATION

Returns all punctuation characters.

3.32 \$ZMATCHALPHABETIC

Returns all alphabetic characters.

3.33 \$ZMATCHLOWERCASE

Returns all lowercase characters.

3.34 \$ZMATCHUPPERCASE

Returns all uppercase characters.

3.35 \$ZMATCHEVERYTHING

Returns control characters, numbers, punctuation, and alphabetic characters.

3.36 \$ZPRECISION

Gets or sets the number of digits of numeric precision used for fixed-point decimal arithmetic. Defaults to 100 digits.

3.37 \$ZREFERENCE

Returns the last *gln* referenced.

3.38 \$ZSYSTEM**3.39 \$ZTIME**

Returns the system time in HH:MM:SS (24-hour) format.

3.40 \$ZTRAP**3.41 \$ZVERSION**

4 Intrinsic Functions

4.1 \$ASCII

Returns the ASCII code (in decimal) for one character in a string.

```
SET RESULT=$ASCII(<string>[,<index>])
```

If *<index>* is not supplied, \$ASCII will return the ASCII code of the first character. Otherwise, returns the ASCII code of the character at position *<index>*.

4.2 \$CHAR

Returns a string of characters corresponding to a list of ASCII codes.

```
SET RESULT=$CHAR(<ascii-code>[,<ascii-code>,...])
```

4.3 \$DATA

Returns a numeric value 0, 1, 10, or 11, depending on whether a referenced node is defined, has data, or has children:

```
SET RESULT=$DATA(<node>)
```

The return values are as follows:

```
0: <node> is undefined  
1: <node> has data but no children  
10: <node> has children but no data  
11: <node> has children and data
```

4.4 \$EXTRACT

4.5 \$FIND

4.6 \$FNUMBER

4.7 \$GET

4.8 \$JUSTIFY

4.9 \$LENGTH

4.10 \$NAME

4.11 \$NEXT

4.12 \$ORDER

4.13 \$PIECE**4.14 \$QLENGTH****4.15 \$QSUBSCRIPT****4.16 \$QUERY****4.17 \$RANDOM****4.18 \$REVERSE****4.19 \$SELECT****4.20 \$STACK****4.21 \$TEXT****4.22 \$TRANSLATE****4.23 \$VIEW****4.24 \$ZBOOLEAN**

Performs *boolean-operation* on numeric arguments *A* and *B*.

Syntax

```
SET RESULT=$ZBOOLEAN(A,B,boolean-operation)
```

\$ZBOOLEAN Operations (*boolean-operation* values)

0	Always <i>false</i>
1	A AND B
2	A AND NOT B
3	A
4	NOT A AND B
5	B
6	A XOR B

5 Commands

5.1 BREAK

Interrupts running routine to allow interactive debugging.

Syntax

`BREAK:postcondition`

In its argumentless form, `BREAK` suspends execution of running code, provided the optional *postcondition* is *true* or omitted.

`BREAK:postcondition breakflag`

In its single-argument form, `BREAK` sets *Ctrl-C* handling and error handling characteristics, provided the optional *postcondition* is *true* or omitted. The following table enumerates the possible values of *breakflag*

0	Disables <i>Ctrl-C</i> handling
-2	Enables normal FreeM error handling
2	Enables <i>Digital Standard MUMPS v2</i> error handling
"default"	Enables <i>Ctrl-C</i> handling

5.2 CLOSE

Closes an input/output device.

Syntax

`CLOSE:postcondition`

In its argumentless form, `CLOSE` closes all I/O devices except for device 0 (the `HOME` device), provided the optional *postcondition* is *true* or omitted.

`CLOSE:postcondition channel`

In its single-argument form, `CLOSE` closes the I/O device associated with channel *channel*, provided that *channel* represents a currently-open device, and the optional *postcondition* is *true* or omitted.

5.3 DO

5.4 ELSE

5.5 FOR

5.6 GOTO

5.7 HALT

5.8 HANG

5.9 IF

5.10 JOB

5.11 KILL

5.12 KSUBSCRIPTS

Kills only the descendant subscripts (but not the data value) of a referenced global, local, or SSV (where allowed).

Syntax

`KSUBSCRIPTS:postcondition var1,...`

In the above *inclusive* form, KVALUE will kill the descendant subscripts at each local, global, or SSV node specified in the list (provided that the optional *postcondition* is *true* or omitted), but will leave the data value intact.

Note The below *argumentless* and *exclusive* forms of KSUBSCRIPTS are not implemented in FreeM, as of version 0.3.3, but are planned for a future release.

`KSUBSCRIPTS:postcondition`

In the above *argumentless* form, KSUBSCRIPTS will kill the descendant subscripts at the root of each local variable (provided that the optional *postcondition* is *true* or omitted), but will leave data values intact.

`KSUBSCRIPTS:postcondition (var1,...)`

In the above *exclusive* form, KSUBSCRIPTS will kill the descendant subscripts of all local variables, *with the exception of* those named in the list, provided that the optional *postcondition* is *true* or omitted, while leaving their data values intact.

5.13 KVALUE

Kills only the data value (but not descendant subscripts) of a referenced global, local, or SSV (where allowed).

Syntax

`KVALUE:postcondition var1,...`

In the above *inclusive* form, KVALUE will kill the data values at each local, global, or SSV node specified in the list (provided that the optional *postcondition* is *true* or omitted), but will leave descendant subscripts intact.

Note The below *argumentless* and *exclusive* forms of KVALUE are not implemented in FreeM, as of version 0.3.4, but are planned for a future release.

KVALUE:postcondition

In the above *argumentless* form, KVALUE will kill the data values at the root of each local variable (provided that the optional *postcondition* is *true* or omitted), but will leave descendant subscripts intact.

KVALUE:postcondition (var1,...)

In the above *exclusive* form, KVALUE will kill the data values of all local variables, *with the exception of* those named in the list, provided that the optional *postcondition* is *true* or omitted, while leaving their descendant subscripts intact.

5.14 LOCK

5.15 MERGE

Merges the contents of one global, local, or SSV subtree to another global, local, or SSV.

Syntax

```
MERGE A=~$JOB
```

The above example will merge the `~$JOB` SSV into the `A` local. Note that the FreeM implementation of MERGE does not yet support multiple merge arguments. Returns error M19 if either the source or the target variable are descendants of each other.

5.16 NEW

5.17 OPEN

Opens sequential I/O devices and files and associates them with a numeric FreeM input/output channel.

Syntax

```
OPEN:postcondition channel:"filename/access-mode"
```

Opens *filename* for reading and/or writing, and associates the file with FreeM I/O channel *channel*, provided that the optional *postcondition* is *true* or omitted. The below table lists the valid options for *access-mode*:

Open-Use-Close File Path

You cannot specify a fully-qualified filesystem path in the FreeM OPEN command. By default, FreeM will assume that *filename* exists in the current directory of the FreeM process. If you wish to access files in other directories, you must first set the *open-use-close file path* with the VIEW 9 command.

The following example will set the open-use-close file path to `/etc`:

```
VIEW 9:"/etc"
```

r	Read-only access
w	Create a new file for write access
a	Write access; append to existing file

r+ Read/write access

If *channel* was already OPENed in the current process, calling OPEN on the same channel again implicitly closes the file or device currently associated with *channel*.

5.18 QUIT

5.19 READ

5.20 SET

5.21 TCOMMIT

5.22 TRESTART

5.23 TROLLBACK

5.24 USE

5.25 VIEW

5.26 WRITE

5.27 XECUTE

5.28 ZALLOCATE

5.29 ZBREAK

5.30 ZDEALLOCATE

5.31 ZGO

5.32 ZHALT

5.33 ZINSERT

5.34 ZJOB

5.35 ZLOAD

5.36 ZNEW

5.37 ZPRINT

5.38 ZQUIT

5.39 ZREMOVE

5.40 ZSAVE

5.41 ZTRAP

5.42 ZWATCH

Sets a watchpoint on a global, local, or SSV node.

Syntax

In its *argumentless* form, ZWATCH toggles watchpoints on and off, provided the optional *postcondition* is *true* or omitted.

```
ZWATCH:postcondition
```

In its *inclusive* form, ZWATCH adds, removes, or examines watchpoints, provided the optional *postcondition* is *true* or omitted.

A + adds a new watchpoint to the following variable.

A - removes an existing watchpoint for the following variable.

A ? examines the status of a watchpoint for the following variable.

```
ZWATCH:postcondition [+|-|?] var1...,[+|-|?] varN
```

The following example demonstrates turning watchpoint processing on and adding a watchpoint for global variable `^jpw(1)`. It then changes the value of `^jpw(1)`.

```
USER [LEGACY]> ZWATCH
```

```
Watchpoints enabled.
```

```
USER [LEGACY]> ZWATCH +^JPW(1)
```

```
Added '^JPW("1")' to the watchlist.
```

```
USER [LEGACY]> SET ^JPW(1)="new value"
```

```
>> WATCHPOINT: ^JPW("1") => 'new value' (changed 1 times)
```

The following example will remove that watchpoint:

```
USER [LEGACY]> ZWATCH -^JPW(1)
```

```
Removed '^JPW("1")' from the watchlist.
```

```
USER [LEGACY]> ZWATCH ?^JPW(1)
```

'^JPW("1")' is not being watched.

5.43 ZWRITE

Writes the names and values of M variables to \$IO.

Syntax

ZWRITE:*postcondition*

In the argumentless form, writes the names and values of all local variables to \$IO if the optional *postcondition* is *true* or omitted.

ZWRITE:*postcondition* *ArrayName*,...

In the inclusive form, writes the names and values of all local, global, or structured system variables specified in the list of *ArrayNames* to \$IO if the optional *postcondition* is *true* or omitted.

ZWRITE:*postcondition* (*ArrayName*,...)

In the exclusive form, writes all local variables *except* those specified in the list of *ArrayNames* to \$IO if the optional *postcondition* is *true* or omitted.

6 Structured System Variables

SSV subscripts are each described in the following format:

```
<ssvn-subscript-name> +/-R +/-U +/-D
```

The R, U, and D flags represent Read, Update, and Delete. A minus sign indicates that the given operation is *not* allowed, and a plus sign indicates that the given operation *is* allowed.

6.1 ^\$CHARACTER

The ^\$CHARACTER SSV is not yet implemented.

6.2 ^\$DEVICE

FreeM implements several important pieces of functionality in the ^\$DEVICE SSV.

The first subscript of ^\$DEVICE represents the I/O channel of an OPENed device.

The following values for the second subscript are supported:

EOF +R -U -D

Returns 1 if the I/O channel has encountered an end-of-file condition; 0 otherwise. Only valid if the I/O channel is connected to a sequential file.

LENGTH +R -U -D

Returns the length of the file connected to the I/O channel. Only valid if the I/O channel is connected to a sequential file.

MNEMONICSPACE +R -U -D

Returns the current *mnemonic-space* in use for the referenced I/O channel. Always X364 for terminals and blank for sequential files.

Example

The following example M code opens `/etc/freem.conf` and reads its contents line-by-line until the end of the file is reached.

```
VIEW 9: "/etc" ; set open/use/close path to /etc
OPEN 1: "freem.conf/r" ; open freem.conf for reading
;
; read until we run out of lines
;
FOR USE 1 READ LINE USE 0 QUIT: ^$DEVICE(1, "EOF") D
. WRITE LINE, !
;
CLOSE 1
QUIT
```

6.3 ^\$DISPLAY

The ^\$DISPLAY SSV is not yet implemented.

6.4 `^$EVENT`

The `^$EVENT` SSV is not yet implemented.

6.5 `^$GLOBAL`

The `^$GLOBAL` SSV is not yet implemented.

6.6 `^$JOB`

FreeM fully implements `^$JOB` per ANSI X11.1-1995, as well as several extensions proposed in the M Millennium Draft Standard.

The first subscript of `^$JOB` represents the `$JOB` of the process.

If you `KILL` a first-level subscript of `^$JOB`, the `SIGTERM` signal will be sent to the corresponding UNIX process, causing pending transactions to be rolled back and the process to be terminated. If the targeted process is in direct mode, the user will be prompted with options of either rolling back or committing any pending transactions.

The following subscripts are supported:

`CHARACTER +R -U -D`

Returns the character set of the job.

`EVENT +R +U +D`

The subtree contained under `^$JOB($J,"EVENT")` defines asynchronous event handlers for the current job. Please see *FreeM Event Handling* for more information.

`GLOBAL +R -U -D`

Returns the global environment of the job.

`ROUTINE +R -U -D`

Returns the name of the routine currently being executed by the job.

`$PRINCIPAL +R -U -D`

Returns the value of `$PRINCIPAL` for the job.

`$TLEVEL +R -U -D`

Returns the current transaction level (value of `$TLEVEL` for the job).

`$IO +R -U -D`

Returns the current value of `$IO` for the job.

`USER +R -U -D`

Returns the UID of the user owning the job.

`GROUP +R -U -D`

Returns the GID of the group owning the job.

`NAMESPACE +R +U -D`

Returns or sets the name of the job's currently-active namespace.

6.7 `^$LOCK`

The `^$LOCK` SSV is not yet implemented.

6.8 `^$PDISPLAY`

The `^$PDISPLAY` SSV is not yet implemented.

6.9 `^$ROUTINE`

The `^$ROUTINE` SSV is not yet implemented.

6.10 `^$SYSTEM`

The `^$SYSTEM` SSV is not yet implemented.

6.11 `^$WINDOW`

The `^$WINDOW` SSV is not yet implemented.

6.12 `^$ZPROCESS`

Provides access to `procfs`, which is a filesystem-like abstraction for UNIX process metadata contained in `/proc`, as well as features for examining and controlling the state of processes external to the FreeM interpreter.

The first subscript always represents the *process ID* of the external process being acted upon.

The following values for the second subscript are supported:

EXISTS +R -U -D

Returns 1 if the referenced process exists; 0 otherwise.

ATTRIBUTES +R -U -D

Exposes the `/proc` files as descendant subscripts, i.e., `WRITE ^$ZPROCESS(2900,"ATTRIBUTES","cmdline"),!` would print the initial command line used to invoke process ID 2900.

SIGNAL -R +U -D

Allows signals to be sent to the referenced process. The following subscript is an integer value corresponding to the desired signal number. You may obtain a list of signal numbers on most UNIX systems with the command `kill -l`.

7 Operators

7.1 Unary +

7.2 Unary -

7.3 + (Add)

7.4 += (Add/Assign)

7.5 ++ (Postfix Increment)

7.6 - (Subtract)

7.7 -= (Subtract/Assign)

7.8 -- (Postfix Decrement)

7.9 * (Multiply)

7.10 *= (Multiply/Assign)

7.11 / (Divide)

7.12 /= (Divide/Assign)

7.13 \ (Integer Divide)

7.14 \= (Integer Divide/Assign)

7.15 # (Modulo)

7.16 #= (Modulo/Assign)

7.17 ** (Exponentiate)

7.18 **= (Exponentiate/Assign)

7.19 < (Less Than)

7.20 <= (Less Than or Equal To)

7.21 > (Greater Than)

7.22 >= (Greater Than or Equal To)

7.23 _ (Concatenate)

7.24 _= (Concatenate/Assign)

7.25 = (Equals)

7.26 [(Contains)

7.27] (Follows)

7.28]] (Sorts After)

7.29 ? (Pattern Match)

7.30 & (Logical AND)

7.31 ! (Logical OR)

7.32 ' (Logical NOT)

7.33 @ (Indirect)

8 User-Defined Z Functions

9 User-Defined SSVs

10 System Library Routines

10.1 `^%ZCOLUMNS`

This routine is the implementation of the `$ZCOLUMNS` intrinsic special variable.

10.2 `^%ZFREEM`

This routine is the default startup routine for FreeM running in direct mode.

Running `DO INFO` from direct mode will use this routine to display information about the current FreeM status and namespace configuration.

10.3 `^%ZHELP`

This routine implements the online help feature of FreeM, invoked by typing `?` in direct mode. It simply asks the underlying system to execute the command `info freem`.

10.4 `^%ZROWS`

This routine is the implementation of the `$ZROWS` intrinsic special variable.

11 System Configuration

11.1 Installing FreeM

11.2 Namespaces Overview

Configuration and administration of FreeM and the applications it hosts centers around the concept of *namespaces*, which represent a collection of M routines and globals existing within a well-defined directory hierarchy.

Beneath the FreeM installation directory (typically `/var/local/freem`) exists a number of subdirectories, each corresponding to a single FreeM namespace.

In the example below, two namespaces have been defined, named `SYSTEM` and `USER`. This is a fairly typical configuration, and routines and globals whose names begin with the `%` character, which are generally considered to be code and data to be shared among all namespaces in a FreeM system, are typically stored in the `SYSTEM` namespace, while each individual application or related set of applications will be managed beneath another namespace, such as the `USER` namespace presented below:

```
$freem_base
+- SYSTEM
| +- routines
| | +- %ZFREEM.m
| | +- %ZCOLUMNS.m
| | +- %ZFRMXEC.m
| | +- %ZFRMSAMP.m
| | +- %ZROWS.m
| | +- %ZHELP.m
| +- globals
|   +- ~%SYS
+- USER
  +- routines
  | +- MYAPP.m
  +- globals
    +- ~MYGLOBAL
```

11.3 Listing Namespaces

To list all namespaces defined in `'freem.conf'`, type the following command:

```
$ namespace list
```

```
Namespaces Defined in /etc/freem.conf:
```

```
SYSTEM
USER
```

In this example, the `SYSTEM` and `USER` namespaces are the only ones defined.

11.4 Adding Namespaces

When adding new applications to your FreeM installation, it is important to plan an appropriate namespace configuration. In general, it is advisable to place each application in its own namespace, as this will prevent conflicts in routine and global names, which can easily lead to data corruption. However, there are cases where it is preferable (or even essential) to combine multiple applications into a single namespace, i.e., when two applications rely on the ability to access each other's routines and/or globals, both applications must reside in a shared namespace.

In order to add a namespace to FreeM, you use the `namespace add` command. In the following example, we will add a new namespace called `MVTS`, for installing the M Validation and Test Suite:

```
$ namespace add MVTS
Adding namespace MVTS...
```

```
Namespace MVTS has been created.
Access it with the following command:
```

```
$ freem --namespace=MVTS
```

Or if FreeM is already running:

```
SYSTEM> SET ^$JOB($JOB,"NAMESPACE")="MVTS"
```

The `namespace` utility supports customization of a great many namespace options, including configuration of journaling and lock table location, among others.

For more information on the `namespace` utility, please consult the relevant section of the manual in Appendix A (FreeM Utilities).

11.5 Removing Namespaces

Not yet implemented.

11.6 Importing Routines

FreeM fully supports the `%R0/%RI` distribution format for the transport of collections of application routines. The `ri` utility, located in `$freem_base/sbin/ri`, will allow you to import such a file directly into a defined namespace with minimal effort.

In this example, we will create a `VPE` namespace and import the *Victory Programming Environment* into it:

```
$ namespace add VPE
Adding namespace VPE...
```

```
Namespace VPE has been created.
Access it with the following command:
```

```
$ freem --namespace=VPE
```

Or if FreeM is already running:

```
SYSTEM> SET ^$JOB($JOB,"NAMESPACE")="VPE"
```

```
$ ri --namespace=VPE --file=VPE15P2.RSA
```

FreeM Routine Import from 'VPE15P2.RSA'

- * Using FreeM namespace VPE
- * Percent routines will be loaded into /home/jpw/.freem/SYSTEM/routines
- * User routines will be loaded into /home/jpw/.freem/VPE/routines

Routines

Routines:

```
XVEMBLDA  
XVEMBLDB  
XVEMBLDL  
XVEMBLD  
XVEMD1  
XVEMDC  
XVEMSYN
```

...lines omitted...

```
XVVMIOOS  
XVVMINI1  
XVVMINI2  
XVVMINI3  
XVVMINI4  
XVVMINI5  
XVVMINIS  
XVVMINIT  
XVVMVPE
```

Loaded 246 user routines and 0 percent routines (246 total).

12 Accessing FreeM from C Programs

FreeM provides a library, ‘libfreem.so’, as well as corresponding header file ‘freem.h’, allowing C programmers to write programs that access FreeM globals, locals, structured system variables, subroutines, and extrinsic functions. This functionality can be used to implement language bindings and database drivers for external systems.

In order to be used in your C programs, your C programs must link with ‘libfreem.so’ and include ‘freem.h’. This will allow your C code access to the function prototypes, data structures, and constants required for calling the ‘libfreem.so’ APIs.

You must exercise caution in developing programs that interface with FreeM through ‘libfreem.so’ to ensure that all ‘libfreem.so’ API calls are serialized, as FreeM and the ‘libfreem.so’ library are neither thread-safe nor reentrant.

You must also avoid setting signal handlers for SIGALRM, as FreeM uses SIGALRM to manage timeouts for LOCK, READ, and WRITE.

12.1 freem_ref_t Data Structure

The libfreem API uses a struct of type freem_ref_t in order to communicate state, pass in values, and return results.

The data structure, defined in ‘freem.h’, looks like this:

```
typedef struct freem_ref_t {

    /*
     * The 'reftype' field can be one of:
     *
     * MREF_RT_LOCAL
     * MREF_RT_GLOBAL
     * MREF_RT_SSV
     */
    short reftype;

    /*
     * The 'name' field is the name of the local variable,
     * global variable, or SSV (without ^ or ^$).
     */
    char name[256];

    /*
     * Returned data goes in a string, so you've got to figure out the
     * whole M canonical number thing yourself. Good luck. :-)
     */
    char value[STRLEN];

    short status;

    unsigned int subscript_count;
```

```

    char subscripts[255][256];

} freem_ref_t;
freem_ref_t Members

```

‘reftype’ The **‘reftype’** member determines whether we are operating on a local variable, a global variable, or a structured system variable. It may be set to any of following constants: **MREF_RT_LOCAL**, **MREF_RT_GLOBAL**, or **MREF_RT_SSV**.

‘name’ The **‘name’** member contains the name of the global, local, or SSV to be accessed. You *must not* include leading characters, such as **^** or **^\$**.

‘value’ This member contains the value read from or the value to be written to the global, local, or SSV.

‘status’ This member gives us various API status values after the API call returns. In general, this value is also returned by each API function.

‘subscript_count’
The number of subscripts to be passed into the API function being called. This value represents the maximum index into the first dimension of the **subscripts** array.

‘subscripts’
A two-dimensional array containing the subscripts to which we are referring in this API call.

12.2 freem_ent_t Data Structure

The **freem_function()** and **freem_procedure()** APIs in **libfreem** use the **freem_ent_t** struct in order to indicate the name of the entry point being called, any arguments being passed to it, and the return value of the called function (not used for **freem_procedure()**).

The data structure, defined in **‘freem.h’**, looks like this:

```

typedef struct freem_ent_t {

    /* name of function or procedure entry point */
    char name[256];

    /* return value */
    char value[STRLEN];

    /* value of ierr on return */
    short status;

    /* argument count and array */
    unsigned int argument_count;
    char arguments[255][256];

} freem_ent_t;

```

freem_ent_t Members

<code>'name'</code>	The <code>'name'</code> member contains the name of the extrinsic function or procedure to be called.
<code>'value'</code>	This member contains the value returned by the function called. Not used by <code>freem_procedure()</code> .
<code>'status'</code>	This member gives us the value of <code>ierr</code> after the function or procedure call returns. The possible values of <code>ierr</code> are listed in <code>merr.h</code> .
<code>'argument_count'</code>	The number of arguments to be passed into the extrinsic function or procedure being called. This value represents the maximum index into the first dimension of the <code>arguments</code> array.
<code>'arguments'</code>	A two-dimensional array containing the arguments to be passed into the extrinsic function or procedure being called.

12.3 freem_init()

Initializes `libfreem` in preparation for calling other APIs.

Synopsis

```
pid_t freem_init(char *namespace_name);
```

Parameters

`namespace_name`

Specifies the namespace to use.

Return Values

Returns the process ID of the `libfreem` process on success, or `-1` on failure.

Example

This example prompts the user to enter a FreeM namespace and then attempts to initialize `libfreem` to use the selected namespace.

```
#include <stdio.h>
#include <string.h>
#include <freem.h>

int main(int argc, char **argv, char **envp)
{
    char namespace[256];

    /* get the namespace name to use */
    printf("Enter FreeM namespace to use: ");
    fgets(namespace, 255, stdin);

    /* remove the trailing newline */
    namespace[strcspn(buffer, "\n")] = '\0';

    /* initialize libfreem using the provided namespace */
```

```

    if(freem_init(namespace) == TRUE) {
        printf("\nSuccess\n");
    }
    else {
        printf("\nFailure\n");
    }

    return 0;
}

```

12.4 freem_version()

Returns the version of FreeM in use.

Synopsis

```
short freem_version(char *result);
```

Parameters

result The **result** parameter is a pointer to a buffer in which the FreeM version information will be returned. The caller must allocate memory for this buffer prior to calling this API. It should be at least 20 bytes in length.

Return Value

Returns 0.

Example

This example will display the FreeM version on standard output.

```

#include <stdio.h>
#include <string.h>
#include <freem.h>

int main(int argc, char **argv, char **envp)
{
    char version[20] = {0};

    freem_init('USER');
    freem_version(version);

    printf('FreeM version: %s\n', version);
}

```

12.5 freem_set()

Sets a FreeM local node, global node, or writable SSV node.

Synopsis

```
short freem_set(freem_ref_t *ref);
```

Parameters

`freem_ref_t`

This parameter is a pointer to a `freem_ref_t` struct. The caller must allocate the memory for this struct.

Return Value

Returns OK on success, or one of the other error values defined in `merr.h`.

Example

This example sets the value `blue` into global node `^car("color")`.

```
#include <stdio.h>
#include <string.h>
#include <freem.h>

int main(int argc, char **argv, char **envp)
{
    freem_ref_t ref;

    /* we're setting a global */
    ref.reftype = MREF_RT_GLOBAL;

    /* access global "car" */
    strcpy(ref.name, "car");

    /* set up the subscripts */
    ref.subscript_count = 1;
    strcpy(ref.subscripts[0], "color");

    /* use the USER namespace */
    freem_init("USER");

    /* write the data out */
    freem_set(&ref);
}
```

12.6 `freem_get()`

Retrieves a FreeM local node, global node, or writable SSV node.

Synopsis

```
short freem_get(freem_ref_t *ref);
```

Parameters

`freem_ref_t`

This parameter is a pointer to a `freem_ref_t` struct. The caller must allocate the memory for this struct.

Return Value

Returns OK on success, or one of the other error values defined in `merr.h`.

Example

This example retrieves the character set of the current process.

```
#include <stdio.h>
#include <sys/types.h>
#include <unistd.h>
#include <string.h>
#include <freem.h>

int main(int argc, char **argv, char)
{
    pid_t pid;
    freem_ref_t ref;

    /* get the PID of this process */
    pid = getpid();

    /* we want to access an SSV */
    ref.reftype = MREF_RT_SSV;

    /* set up the name and subscripts */
    strcpy(ref.name, "JOB");

    ref.subscript_count = 2;
    sprintf(ref.subscripts[0], "%d", pid);
    strcpy(ref.subscripts[1], "CHARACTER");

    /* initialize libfreem, using the USER namespace */
    freem_init("USER");

    /* call libfreem API */
    freem_get(&ref);

    /* output the character set info */
    printf("PID %d character set is '%s'\n", pid, ref.value);
}
```

12.7 `freem_kill()`

Deletes a FreeM local node, global node, or killable SSV node, as well as all of its children.

```
short freem_kill(freem_ref_t *ref);
```

Parameters

`freem_ref_t`

This parameter is a pointer to a `freem_ref_t` struct. The caller must allocate the memory for this struct.

Return Value

Returns OK on success, or one of the other error values defined in `merr.h`.

Example

```
#include <stdio.h>
#include <string.h>
#include <freem.h>

int main(int argc, char **argv, char **envp)
{
    freem_ref_t ref;

    /* we're killing a global node */
    ref.reftype = MREF_RT_GLOBAL;

    /* access global "car" */
    strcpy(ref.name, "car");

    /* set up the subscripts */
    ref.subscript_count = 0;

    /* use the USER namespace */
    freem_init("USER");

    /* kill the global and all its descendant subscripts */
    freem_kill(&ref);
}
```

12.8 freem_data()**12.9 freem_order()****12.10 freem_query()****12.11 freem_lock()****12.12 freem_unlock()****12.13 freem_tstart()****12.14 freem_trestart()****12.15 freem_trollback()**

12.18 `freem_function()`

12.19 `freem_procedure()`

Appendix A FreeM Utilities

A.1 Global Compactor (gcompact)

Compacts the specified global in place.

Syntax

```
gcompact /path/to/global/file
```

A.2 Block Examiner (gfix)

The *gfix* interactive utility program permits navigation of the B-tree structure of the specified global a block at a time.

Syntax

```
gfix </path/to/global/file>
```

A.3 Global Lister (gl)

This utility lists the contents of the specified global in various formats to standard output.

Syntax

```
gl [OPTIONS] </path/to/global/file>
```

- '-k' Show global keys alone on a separate line.
- '-d' Show global data alone on a separate line.
- '-n' Show global keys and data, each on a separate line, with the keys in naked indicator form relative to the previous key.

If none of these options are supplied, the output has each node's key and data on the same line separated by an = sign. The '-k' and '-d' switches may be combined as '-kd' in order to output keys and data on alternating lines.

A.4 Lock Examiner (glocks)

This utility lists the contents of the lock table to standard output.

Syntax

```
glocks [OPTIONS...] [</path/to/global/file>]
```

Options

- '-pid <process-id>' Causes all locks owned by <process-id> to be cleared from the lock table.

A.5 Global Repair Tool (grestore)

This utility will fix problems with the specified global.

Syntax

```
grestore </path/to/global/file>
```

A.6 Global Validator (gverify)

This utility checks the specified global file for database corruption and inconsistencies.

Syntax

```
gverify <path/to/global/file>
```

A.7 Namespace Manager (namespace)

Adds, removes, lists, or displays the configuration of FreeM namespaces, allowing the user to specify all relevant configuration options.

Syntax

```
namespace [add | remove | show] [-n <namespace> | --namespace=<namespace>]
          [OPTIONS...]
namespace list
```

Options

‘-h’, ‘--help’

Displays a summary of `namespace` syntax and command-line options.

‘-n <namespace>’, ‘--namespace=<namespace>’

Sets the namespace being acted upon.

‘-m [inactive | read | write]’, ‘--jnlmode=[inactive | read | write]’

Sets the journaling mode for the namespace; ‘inactive’ by default.

‘-f <journal-file>’, ‘--jnlfile=<journal-file>’

Sets the file that FreeM will use for journaling; ‘/tmp/freem.journal’ by default.

‘-l <locktab-file>’, ‘--locktab=<locktab-file>’

Sets the file that FreeM will use for maintaining the LOCK table; ‘/tmp/freem.locktab’ by default.

‘-z <zalloctab-file>’, ‘--zalloctab=<zalloctab-file>’

Sets the file that FreeM will use for maintaining the ZALLOCATE table; ‘/tmp/freem.zalloctab’ by default.

‘-c <hardcopy-file>’, ‘--hardcopy=<hardcopy-file>’

Sets the file FreeM will use when invoked in hardcopy mode; ‘/tmp/freem.hardcopy’ by default.

‘-r <rga-file>’, ‘--rgafile=<rga-file>’

Sets the file where FreeM will log routine and global accesses; ‘/tmp/freem.rgafile’ by default.

‘-p <freem-path>’, ‘--path=<freem-path>’

Informs this program of the location where FreeM is installed. You must supply the ‘-p’ or ‘--path’ option if the `$freem_base` environment variable is not set.

A.8 Routine Import (ri)

Allows the user to import routines in the %R0/%RI distribution format into a FreeM namespace.

Syntax

```
ri --file=<archive-file> --namespace=<namespace-name> [--overwrite]
```

Options

'--file=<archive-file>'

Specifies the %R0/%RI-format file whose routines you wish to import.

'--namespace=<namespace-name>'

Specifies the FreeM namespace into which routines from <archive-file> will be loaded.

'--overwrite'

Indicates that `ri` should overwrite any routines from <archive-file> that already exist in <namespace-name>. Use with a preponderance of caution.

Appendix B FreeM VIEW Commands and Functions

B.1 VIEW 1: Terminal Device Status Word

Allows the user to retrieve or set the terminal Device Status Word

B.2 VIEW 2: Current Directory Path

Allows the user to retrieve or set the current filesystem directory path of the FreeM process.

Syntax

```
VIEW 2: "/etc" ; sets the directory path to /etc
```

B.3 VIEW 3: Non-Percent Global Access Path

Allows the user to retrieve or set the filesystem path that will be searched for non-percent globals.

Syntax

This example will cause FreeM to search the current directory (.) and /home/jpw/myGlobals for non-percent globals. The first location containing a matching global will be used.

```
VIEW 3: " ./home/jpw/myGlobals"
```

Namespace Warning This VIEW command will override the configured behavior of the current namespace, and should thus be used with great caution.

B.4 VIEW 4: DO/GOTO/JOB Non-Percent Routine Access Path

Allows the user to retrieve or set the filesystem path that will be searched for non-percent routines when using the DO, GOTO, and JOB commands.

Syntax

This example will cause FreeM to search the current directory (.) and /home/jpw/myRoutines for non-percent routines when using DO, GOTO, or JOB. The first location containing a matching routine will be used.

```
VIEW 4: " ./home/jpw/myRoutines"
```

Namespace Warning This VIEW command will override the configured behavior of the current namespace, and should thus be used with great caution.

B.5 VIEW 5: ZLOAD/ZSAVE Non-Percent Routine Access Path

Allows the user to retrieve or set the filesystem path that will be searched for non-percent routines when using the ZLOAD and ZSAVE commands.

Syntax

This example will cause FreeM to search the current directory (.) and /home/jpw/myRoutines for non-percent routines when using ZLOAD or ZSAVE. The first location containing a matching routine will be used.

```
VIEW 5:"./home/jpw/myRoutines"
```

Namespace Warning This VIEW command will override the configured behavior of the current namespace, and should thus be used with great caution.

B.6 VIEW 6: Percent Global Access Path

Allows the user to retrieve or set the filesystem path that will be searched for percent globals.

Syntax

This example will cause FreeM to search the current directory (.) and /home/jpw/myPctGlobals for percent globals. The first location containing a matching global will be used.

```
VIEW 6:"./home/jpw/myPctGlobals"
```

Namespace Warning This VIEW command will override the configured behavior of the current namespace, and should thus be used with great caution.

B.7 VIEW 7: DO/GOTO/JOB Percent Routine Access Path

Allows the user to retrieve or set the filesystem path that will be searched for percent routines when using the DO, GOTO, and JOB commands.

Syntax

This example will cause FreeM to search the current directory (.) and /home/jpw/myPctRoutines for percent routines when using DO, GOTO, or JOB. The first location containing a matching routine will be used.

```
VIEW 7:"./home/jpw/myRoutines"
```

Namespace Warning This VIEW command will override the configured behavior of the current namespace, and should thus be used with great caution.

B.8 VIEW 8: ZLOAD/ZSAVE Percent Routine Access Path

Allows the user to retrieve or set the filesystem path that will be searched for percent routines when using the ZLOAD and ZSAVE commands.

Syntax

This example will cause FreeM to search the current directory (.) and /home/jpw/myPctRoutines for percent routines when using ZLOAD or ZSAVE. The first location containing a matching routine will be used.

```
VIEW 8:"../home/jpw/myRoutines"
```

Namespace Warning This VIEW command will override the configured behavior of the current namespace, and should thus be used with great caution.

B.9 VIEW 9: OPEN/USE/CLOSE Path

Allows the user to retrieve or specify the path used when a sequential file is OPENed.

Syntax

```
;; Read the first two lines of /etc/freem.conf
VIEW 9:"/etc"
OPEN 3:"freem.conf/r"
USE 3
READ LINES(1)
READ LINES(2)
USE 0
SET SUB=""
FOR SET SUB=$ORDER(LINES(SUB)) QUIT:SUB="" WRITE LINES(SUB),!
QUIT
```

B.10 VIEW 10: ZALLOCATE File

Allows the user to retrieve or specify the path to the file used to track ZALLOCATE table entries.

B.11 VIEW 11: LOCK Table File

Allows the user to retrieve or specify the path to the file used to track LOCK table entries.

B.12 VIEW 12: Routine/Global Access Protocol File

Allows the user to retrieve or specify the path to the file used for routine/global access protocol logging.

B.13 VIEW 13: Hardcopy File

Allows the user to retrieve or specify the path to the file used to log WRITE output directed to input/output channel 0 when hardcopy mode is enabled.

B.14 VIEW 16: Total Count of Error Messages/View Single Error Message

Unknown semantics

B.15 VIEW 17: Intrinsic Z-Commands

Allows the user to retrieve or specify the list of intrinsic Z-commands that FreeM will attempt to run internally, allowing intrinsic Z-commands implemented internally to be replaced with M equivalents implemented as %-routines in the `SYSTEM` namespace.

B.16 VIEW 18: Intrinsic Z-Functions

Allows the user to retrieve or specify the list of intrinsic Z-functions that FreeM will attempt to run internally, allowing intrinsic Z-functions implemented internally to be replaced with M equivalents implemented as %-routines in the `SYSTEM` namespace.

B.17 VIEW 19: Intrinsic Special Variables

Allows the user to retrieve or specify which special variables are implemented internally.

B.18 VIEW 20: Break Service Code

Allows the user to view or specify the code that will be run when a `BREAK` is encountered.

B.19 VIEW 21: View Size of Last Global

Allows the user to view the size of the last referenced global.

B.20 VIEW 22: Count VIEW 22 Aliases

Retrieves the number of VIEW 22 aliases in effect.

B.21 VIEW 23: View Contents of Input Buffer

Retrieves the contents of the I/O input buffer.

B.22 VIEW 24: Maximum Number of Screen Rows

Retrieves the maximum number of screen rows supported in the current FreeM build.

B.23 VIEW 25: Maximum Number of Screen Columns

Retrieves the maximum number of screen columns supported in the current FreeM build.

B.24 VIEW 26: DO/FOR/XECUTE Stack Pointer

Retrieves the `DO`, `FOR`, and `XECUTE` stack pointer.

B.25 VIEW 27: DO/FOR/XECUTE Stack Pointer (On Error)

Retrieves the `DO`, `FOR`, and `XECUTE` stack pointer (on error).

B.26 VIEW 28: Switch Symbol Table

Switches the symbol table? We aren't currently aware of what this means.

B.27 VIEW 29: Copy Symbol Table

Copies the symbol table? We aren't currently aware of what this means.

B.28 VIEW 30: Inspect Arguments

Retrieves the arguments passed to the `freem` executable.

B.29 VIEW 31: Count Environment Variables

Allows the user to inspect the number of variables in the process environment table.

Syntax

```
WRITE $VIEW(31),!
```

032	<space>
033	!
034	"
035	#

working on a Windows machine, you must take care to follow this, as Windows will use a carriage return followed by a linefeed by default.

This project follows a modified version of what is known as the Stroustrup indentation style.

E.4 Brace Placement (Functions)

We use modern, ANSI-style function prototypes, with the type specifier on the same line as the function name. You may encounter other styles in the code, but we are transitioning to the new style as time permits.

Below is a correct example:

```
int main(int argc, char **argv, char **envp)
{

}
```

E.5 Brace Placement (if-for-while-do)

The `if` keyword should be followed by one space, then the opening paren and conditional expression. We also use Stroustrup-style `else` blocks, rather than the K&R 'cuddled' `else`:

```
if (x) {
...
}
else {
...
}

while (1) {
...
}

for (i = 1; i < 10; i++) {
...
}

do {
...
} while (x);
```

Single-statement if blocks should be isolated to a single line:

```
if (x) stmt();
not:
if(x)
    stmt();
```

Notice that there is a space between `if` and `(x)`, but not between `stmt` and `()`. This should be followed throughout the code.

If an `if` block has an `else if` or `else`, all parts of the construct must be bracketed, even if one or more of them contain only one statement:

```
if (x) {
    foo();
}
else if (y) {
    bar();
}
else {
    bas();
}
```

E.6 Labels and goto

Labels must begin in column 1, and have two lines of vertical space above and one beneath.

E.7 Preprocessor Conditionals

E.8 coding standards, preprocessor conditionals

I have struggled with this, but have settled upon the standard practice of keeping them in column 1.

E.9 Overall Program Spacing

- Variable declarations fall immediately beneath the opening curly brace, and should initialize the variable right there whenever initialization is used.
- One line between the last variable declaration and the first line of real code.
- The `return` statement of a function (when used as the last line of a function) should have one blank line above it and none below it.
- Really long functions (those whose entire body is longer than 24 lines) should have a comment immediately following the closing curly brace of the function, telling you what function the closing brace terminates.

E.10 The `switch()` Statement

We indent `case` one level beneath `switch()`, and the code within each `case` beneath the `case`. Each `case` should have one line of vertical whitespace above it:

```
switch(foo) {

    case some_const:
        foo();

        break;

    case some_other_const:
        bar();

        break;
```

```
    default:  
        exit(1);  
  
        break;  
}
```

E.11 Comments

We use C-style comments (`/* comment */`) exclusively, even on single-line comments. C++ comments (`// comment`) are not permitted.
